## Question 1

Let  $Z \sim N(0,1)$ , a stand normal distribution and let  $X \sim N(\mu\sigma^2)$ . Let  $\Phi(z)$  be the cdf of  $Z$ . Suppose  $X \sim N(-4,16)$ ; find.

It helps to know that

$$P(X < x) = \Phi\left(\frac{x - \mu}{\sigma}\right).$$

1.  $P(X > 2)$ .

$$\begin{aligned} P(X > 2) &= 1 - P(X < 2) &&= 1 - \Phi\left(\frac{2 - (-4)}{\sqrt{16}}\right) \\ &= 1 - .9332 \\ &= .0688 \end{aligned}$$

2.  $P(0 < X < 4)$

$$\begin{aligned} P(0 < X < 4) &= P(X < 4) - P(X < 0) \\ &= \Phi\left(\frac{4 - (-4)}{4}\right) - \Phi\left(\frac{0 - (-4)}{4}\right) \\ &= .1539 \end{aligned}$$

3.  $P(|X + 3| \geq 3)$

$$\begin{aligned} P(|X + 3| \geq 3) &= P(X \geq 0) + P(X \leq -6) \\ &= 1 - \Phi\left(\frac{4}{4}\right) + \Phi\left(\frac{-2}{4}\right) \\ &= .1587 + .3085 \\ &= .4672 \end{aligned}$$

4.  $P(X \leq 0 \text{ or } X \geq 3)$

$$\begin{aligned} P(X \leq 0 \text{ or } X \geq 3) &= P(X \leq 0) + P(X \geq 3) \\ &= \Phi\left(\frac{4}{4}\right) + 1 - \Phi\left(\frac{7}{4}\right) \\ &= .8413 + .0003 \\ &= .8416 \end{aligned}$$

## Question 2

Based on student A's performance during the first two weeks of a course, the professor has approximately a normal  $N(70, 8^2)$  prior distribution about the student's true ability, on a scale of 0 to 100.

Consider the midterm examination as an error-prone measure of the student's true ability, where if the true ability is  $x$ , the examination score can be modeled as approximately normally distributed,  $N(x, 6^2)$ . The student scores 90 on the midterm.

1. What are the posterior expectation and the probability that the student's true ability is above 85?

WE HAVE the following information.

$$f(\theta) \sim N(70, 8^2)$$

and

$$f(x | \theta) \sim N(x, 6^2)$$

Using Bayes,  $f(\theta | X) \propto f(x | \theta)f(\theta)$  the posterior distribution is

$$(\theta | X) = \frac{1}{\sqrt{2\pi}B} e^{-\frac{(\theta-A)^2}{2B^2}}$$

Where

$$A = \frac{6^2(70) + 8^2(90)}{6^2 + 8^2}$$

and

$$B^2 = \frac{6^2 * 8^2}{6^2 + 8^2}$$

Which give us a  $N(82.8, 23.4)$  posterier distribution and means posterior of expectation of the student's true ability it 82.8. Using the the method from question 1, there is a .4625 probability that the students true ability is above 85.

2. Above 90?

.3792

### Question 3

A "psychic" uses a five-card deck of cards to demenonstrate ESP, and claims to be able to guess a card correctly with probability .5. A single experiment consists of making five guesses, reshuffling the deck after each guess. The experiment is treid and the "pyschic" guesses correctly 3 times out of give. Assuming the only two possibilities are "ESP" and "ordinary guessing", how how must the a priori ability be that "psychic" has ESP is at atleast .7?

Let  $P(\theta)$  be the prior probability that an individual has ESP that we wish to find.

Bayes theorem is

$$P(\theta | X) = \frac{P(X | \theta)P(\theta)}{\sum_{i=1}^2 P(X | \theta_i)P(\theta_i)}.$$

Where we can think of  $P(\theta_1) = P(\theta)$  and  $P(\theta_2) = 1 - P(\theta)$

Plugging in the observed data along with guessing probabilities provided.

$$P(X = 3 | \theta) = \binom{5}{3} (.5)^3 (.5)^2 = .3125$$

and

$$P(X = 3 | \theta_2) = \binom{5}{3} (.2)^3 (.8)^2 = .0512.$$

We can plug these values into Bayes and solve for  $P(\theta | X) \leq .7$ . Ie

$$.7 \leq \frac{.3125P(\theta)}{.3125P(\theta) + .0512(1 - P(\theta))}$$

Which gives  $P(\theta) \geq .276$

#### Question 4

Suppose  $\hat{\theta}_1$  and  $\hat{\theta}_2$  are uncorrelated and both are unbiased estimators of  $\theta$ , and that  $\text{Var}(\hat{\theta}_1) = 2\text{Var}(\hat{\theta}_2)$ .

1. Show that for any constant  $c$ , the weighted average  $\hat{\theta}_3 = c\hat{\theta}_1 + (1 - c)\hat{\theta}_2$  is an unbiased estimator of  $\theta$ .

$$\begin{aligned} E(\hat{\theta}_3) &= cE(\hat{\theta}_1) + (1 - c)E(\hat{\theta}_2) \\ &= c\theta + (1 - c)\theta \\ &= \theta \end{aligned}$$

Hence  $B(\hat{\theta}_3) = 0$ .

2. Find  $c$  for which  $\hat{\theta}_3$  has the smallest MSE.

The MSE of  $\hat{\theta}_3$  is

$$c^2\text{Var}(\hat{\theta}_1) + (1 - c)^2\text{Var}(\hat{\theta}_2)$$

We can find the value,  $c$ , that minimizes MSE by evaluating.

$$\begin{aligned}
MSE(\hat{\theta}_3) &= c^2 \text{Var}(\hat{\theta}_1) + (1-c)^2 \text{Var}(\hat{\theta}_2) \\
&= c^2 2 \text{Var}(\hat{\theta}_2) + (1-c)^2 \text{Var}(\hat{\theta}_2) \\
&= \text{Var}(\hat{\theta}_2)(3c^2 - 2c + 1)
\end{aligned}$$

Setting the above equal to 0 results in  $c = \frac{1}{3}$ . Furthermore, the second derivative of the MSE is positive so we can confirm that  $c$  minimizes.

3. Are there any values of  $c$ ,  $0 \leq c \leq 1$  for which  $\hat{\theta}_3$  is better (in the sense of MSE) than both  $\hat{\theta}_1$  and  $\hat{\theta}_2$

WE ARE given that  $\text{Var}(\hat{\theta}_2)$  is less than  $\text{Var}(\hat{\theta}_1)$ . Since the bias as zero, the MSE is just the variance of each estimator.

$$\begin{aligned}
MSE \hat{\theta}_3 &= c^2 \text{Var}(\hat{\theta}_1) + (1-c)^2 \text{Var}(\hat{\theta}_2) \\
&= c^2 2 \text{Var}(\hat{\theta}_2) + (1-c)^2 \text{Var}(\hat{\theta}_2) \\
&=
\end{aligned}$$
